

Introduction to Telephony

APRICOT2009 VoIP Workshop

Manila, February 2009

Jonny Martin - jonny@jonnynet.net

Daniel Griggs - daniel@ninja.geek.nz

Analogue Telephony

- Where it all started!
- PSTN allows connection between any two endpoints
- Human speech typically in the range 250 - 3,000Hz
 - Humans can hear in the region of 20 - 20,000Hz
- PSTN analogue channel originally designed to carry 300 - 3,500Hz
- Most analogue lines delivered via copper from the local exchange (or CO, Central Office)
 - Average line in NZ ~3Km. Longest lines >7Km

Analogue Telephony

- Even in the day and age of VoIP, this is still important!
 - Analogue telephone adapters (ATAs)
 - Fax - it just won't go away :)
 - Echo
 - Voice and sound is most definitely analogue
 - First and last conversions in a VoIP call

The Analogue Telephone

- Analogue telephones connect to a copper pair
 - A two wire circuit
- Analogue telephones are comprised of five major parts:
 - Ringer
 - Dial Pad
 - Hybrid
 - Hook switch
 - Handset

Ringer

- The exchange provides DC ($\sim 48\text{VDC}$) to power the phone
 - Exchange = big centralised UPS
- Exchange provides a burst of AC ($\sim 80\text{VAC}$) to ring the phone's bell
 - Originally a mechanical bell, these days an electronic buzzer
- These days phone have a Ringer Equivalence Number (REN)
 - Exchange can power up to a sum of 5 RENs
 - Phones these days typically < 0.5 REN
 - ATAs have same limitation

Dial Pad

- Telephones need to signal back to the exchange
- Originally done with a rotary dialler making and breaking the copper loop
 - Pulse Dial, still typically supported by exchanges and some VoIP kit
- All done with audio tones now
 - Dual Tone Multi Frequency (DTMF)
 - Telephone handsets a matrix of switches
 - One tone per column, one per row
 - Each switch generates two tones, hence Dual Tone

DTMF Tones

	1209 Hz	1336 Hz	1477 Hz	1633 Hz
697 Hz	1	2	3	A
770 Hz	4	5	6	B
852 Hz	7	8	9	C
941 Hz	*	0	#	D

Hybrid Network

- The heart of an analogue telephone
- The transformer that couples two signals onto one line
 - Send (Tx) and receive (Rx)
- Creates sidetone ('good echo')
 - Allow speaker to hear himself
- Creates echo unless perfectly balanced

Hook Switch

- Telephone uses it to signal state to the exchange
 - On Hook, closes the copper loop
 - Phone idles, waiting for incoming ring
 - Off Hook, breaks the copper loop
 - Requests dial tone from the exchange, and then allows audio to pass
- Also used to signal 'advanced' features, e.g. call waiting
 - Hook Flash - a timed closure of the hook switch, typically ~300ms

Tip and Ring

- Telephony world often refers to 'Tip' and 'Ring'
- Historical term from the days when exchanges were literally switchboards
- Operator manually patched lines together
- Tip (red) = +ve polarity (0v)
- Ring (green) = -ve polarity
 - -48v on hook, -7v off hook

Telephone and Line Impedance

- Impedance = technical way of saying resistance
 - Varies with both frequency and phase
- American telephone impedance is 600 ohms
 - Approximation of the impedance of 0.4mm twisted copper pair at voice frequencies
- British (and NZ) telephone impedance is complex (in the resistive sense of the word), called BT3
 - 370 ohms in series with (620 ohms in parallel 310nF)
 - Attempt to better match line impedance

Echo

- VoIP does not cause Echo!
 - Hybrids cause echo
 - Echo becomes apparent as latency increases
 - VoIP creates higher latency than circuit switched circuits
- Hybrids must be balanced to the line to effect maximum power transfer and minimal signal reflection
 - Reflection back down the line = echo
 - Reflection back towards the handset = sidetone

Echo - Telephone Hybrid

Echo

- Sidetone is used to let the user know that the phone 'is working'
 - It's somewhat unnatural to not hear oneself
 - Too much sidetone and you can only hear yourself
 - Too little and it appears the line is dead
- Echo is present on most lines
 - When latency is low ($< 20\text{ms}$ or so) the far end perceives it as sidetone

Acoustic Echo

- Caused by the output of the handset's speaker entering the microphone
 - Due to the speaker volume being too loud or microphone sensitivity too loud
 - Very bad with softphones when not using a headset
 - Or flimsy handset construction (acoustic coupling through the handset itself)
 - The telephone handset design hasn't changed much over the years as it is a very good one!
- Indistinguishable to the far end from echo caused by the local hybrid

Reducing Echo

- There are only four ways to reduce echo
 - Remove the two wire (analogue) portion of the call
 - Balance the analogue portion of the call better
 - Hard to do even if you do have access to the endpoint(s)
 - Reduce the latency
 - Often impossible, e.g. long distance calls
- Cancel the echo

Echo Cancellers

- Measure signal on the line, predict the echo, and create a signal to cancel it
- Echo cancellers are configured for a 'tail' length - the maximum latency of an echo which it can possibly cancel
- Takes time to converge to an echo cancelled state, dependant on the tail length of the canceller
- Echo cancellers aren't perfect, so best to prevent echo in the first place
- Popular misconception that software based echo cancellation is bad.
 - Hardware echo cancellers have very good, often patented algorithms
 - No really good open source software implementations (yet...)
 - Software echo cancellation is not bad - if you have a good algorithm!

Digital Telephony

- Telephony moved digital for the same reason everything else did
- Voice turned to a digital signal using Pulse Code Modulation (PCM)
 - Sample signal in time
- Two important factors:
 - Number of samples per second (highest frequency is half of the sample rate - Nyquist's Theorem)
 - Number of bits used to encode signal
- Tradeoff between quality and bandwidth - standard is 8bits at 8kHz sampling

Digital Telephony

- Standard voice channel (timeslot, or DS0) is 64kbit/s
- Most common codec is G711, a companding codec
 - Two types, ulaw (US) and alaw (Europe)
- Majority of telephone conversation is 'quiet'
- More bits are allocated to quiet signals to improve overall quality

Figure 7-12. Quantized and companded at 5-bit resolution from Asterisk, The Future of Telephony

PSTN Circuits

- Analog line
- ISDN
 - Basic rate, two voice 64kbit/s voice channels + 16kbit/s data channel -> 144kb/s
 - Primary rate
 - US - T1, 24 64kbit/s voice channels -> 1.544Mb/s line rate
 - Europe - E1, 30 64kbit/s voice channels -> 2.048Mb/s line rate
- Proprietary circuits between key phones and PBXs - not covered here

VoIP

- Natural progression from digital telephony
 - Circuit switched --> packet switched
 - Still a need to sample and encode signals
- Many different codecs in the VoIP world
- Many different signalling protocols

Codecs

Codec	Payload Bitrate
G.711	64 kbit/s
G.726	16,24, or 32 kbit/s
G.723.1	5.3 or 6.3 kbit/s
G.729	8 kbit/s
GSM	13 kbit/s
iLBC	13.3 or 15.2 kbit/s
Speex	2.15 to 22.4 kbit/s

- G711 gives highest quality
- Some wide bandwidth codecs supported now
- GSM very popular - good CPU time vs. bandwidth tradeoff
- Speex well suited to changing network conditions

Signalling Protocols

- Signalling protocols needed to allow endpoints and intermediary devices to set up calls
- Common VoIP signalling protocols:
 - H.323
 - MGCP (Media Gateway Control Protocol)
 - Skinny / SCCP (Skinny Client Control Protocol)
 - IAX (Inter Asterisk eXchange)
 - SIP (Session Initiation Protocol)

H.323

- 10 year old ITU protocol developed to carry multimedia traffic across an IP network
 - Actually a suite of protocols, the signalling component being H.245
 - Originally designed for video conferencing
- Quickly became de-facto standard for VoIP - and is still used today in many large carrier environments
- Relatively secure and bug free due to its maturity
- Does not work well with NAT at all
- Has all but disappeared in end stations over the past few years

MGCP

- IETF standard, RFC 3345 (obsoletes RFC2705)
- Still widely deployed
 - Slowly being displaced by SIP
- Being a gateway protocol, has very good gateway features useful for a carrier environment
- Some end phone support for MGCP but never big

Skinny / SCCP

- Cisco Proprietary protocol
 - Originally developed by Selius Systems in the mid 1990's
 - Cisco bought them and entered the telephony market :)
- Cisco CallManager based on Skinny, though finally moving to the more standard SIP
- Called Skinny as phones are 'dumb'.
 - SCCP phone events: button X pressed, turn on lamp X, turn off lamp X

IAX

- Developed by Digium, creators of Asterisk
 - Apparently it's pronounced "eeks". I still say "eye-aye-ex"
- Primarily designed to connect Asterisk servers together
 - Has unique ability to trunk multiple calls down one dataflow
 - Includes some extra signalling
 - Uses a single UDP port, so NAT friendly
 - Can use plaintext, MD5, or RSA key exchange for authentication
- IAX, although open source, is not a widely adopted standard

SIP

- SIP is *the* VoIP protocol these days - RFC 3261 (obsoletes RFC 2543)
- Original (simple!) draft created in 1996
- We'll be concentrating on SIP and largely ignoring the rest
 - It is worth playing around with IAX if you are going to be using Asterisk
- Largely ignored early on it's life (H.323 was used)
- Largely standard implementations of SIP now
- Not overly NAT friendly, although workarounds exist
- Worthy of a more in-depth look!

What is SIP?

“Session Initiation Protocol (SIP),

an application-layer control (signaling) protocol for creating, modifying, and terminating sessions with one or more participants”

(RFC 3261)

SIP Overview

- ASCII based signalling protocol
- Analogous to HTTP messages
- Works independent of the underlying network transmission protocol
- Provides mechanisms to:
 - Establish a session
 - Maintain a session
 - Modify and Terminate a session

SIP Overview

- Strength is it's simplicity and basic assumptions
- Component reuse
 - A child of SMTP and HTTP
 - SIP also uses MIME to carry extra information
 - Uses URI Eg: sip:jonnyphone@jonnynet.net

SIP Overview

- Scalable and robust protocol
 - Can offload various separate SIP functions to dedicated servers
 - Uses distributed architecture
- Very inter-operable protocol (well, these days it is!)
- Supports mobility through use of endpoint registration
- Uses RTP to carry media

SIP elements

- SIP User Agents
 - User Agent Clients (UAC) - the entity which initiates a call
 - User Agent Servers (UAS) - the entity which receives a call
- SIP Servers
 - Registrar server
 - Proxy server
 - Location server
 - Redirect server

SIP Registrar Server

- Users send registration requests to Registrar server
- Keeps track of client locations
- Supports various forms of authentication
- Often combined with the functionality of a Proxy server (Asterisk does this)

SIP Proxy Server

- Acts both as a server and a client
- Receives SIP messages, forwards to next SIP server
- Can perform functions such as Authentication, Authorisation, and Accounting (AAA)
- Provides network access control
- Requests are serviced internally or by passing them on to other servers.
- Interprets, rewrites or translates a request message before forwarding it.

SIP Messages

SIP Methods:

- INVITE – Initiates a call by inviting user to participate in session.
- ACK - Confirms that the client has received a final response to an INVITE request.
- BYE - Indicates termination of the call.
- CANCEL - Cancels a pending request.
- REGISTER – Registers the user agent.
- OPTIONS – Used to query the capabilities of a server.
- INFO – Used to carry out-of-bound information, such as DTMF digits.

SIP Responses:

- 1xx - Informational Messages
 - 180 ringing
- 2xx - Successful Responses
 - 200 OK
- 3xx - Redirection Responses
 - 302 Moved Temporarily
- 4xx - Request Failure Responses.
 - 404 Not Found
- 5xx - Server Failure Responses.
 - 503 Service Unavailable
- 6xx - Global Failures Responses.
 - 600 Busy Everywhere

SIP Messages

Informational

- 100 Trying
- 180 Ringing
- 181 Call forwarded
- 182 Queued
- 183 Session Progress

Success

- 200 OK

Redirection

- 300 Multiple Choices
- 301 Moved Perm.
- 302 Moved Temp.
- 380 Alternative Serv.

Request Failure

- 400 Bad Request
- 401 Unauthorised
- 403 Forbidden
- 404 Not Found
- 405 Bad Method
- 415 Unsupported Content
- 420 Bad Extensions
- 486 Busy Here

SIP Messages

Server Failure

- 504 Timeout
- 503 Unavailable
- 501 Not Implemented
- 500 Server Error

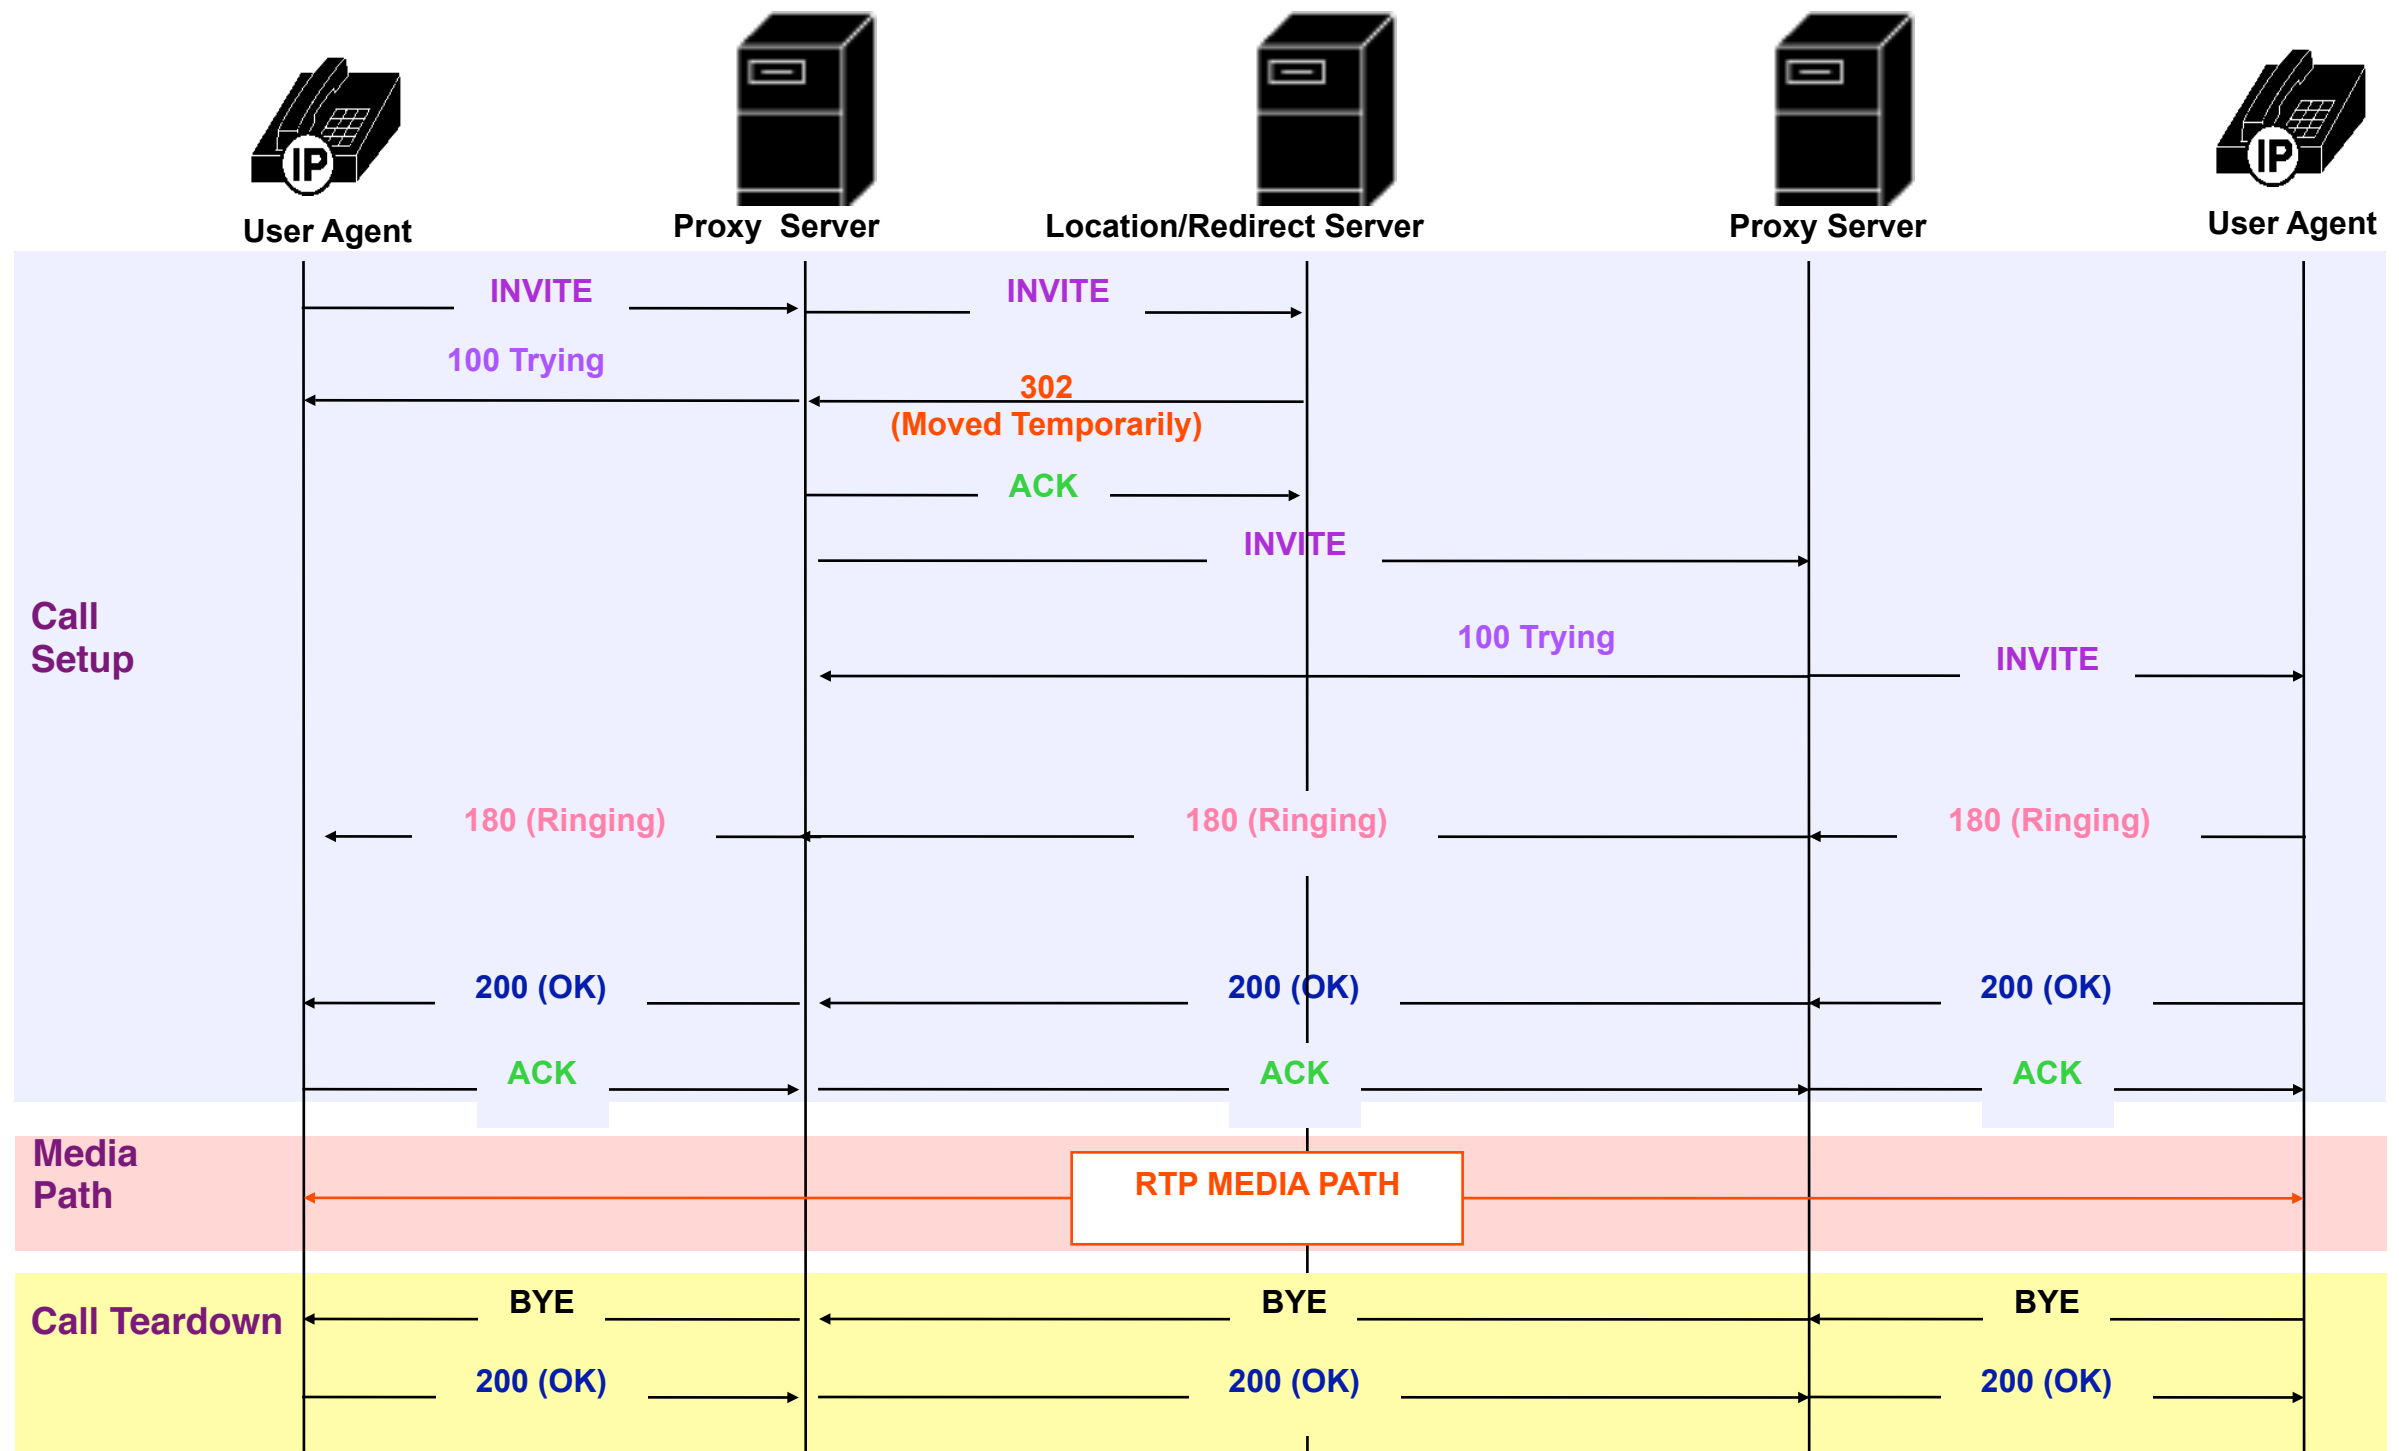

Global Failure

- 600 Busy Everywhere
- 603 Decline
- 604 Doesn't Exist
- 606 Not Acceptable

SIP Addressing

- Can use SMTP style addressing
 - sip:jonnyphone@jonnynet.net
- Or E.164 (telephone number) addressing
 - sip:64212304323@jonnynet.net

Example SIP Call Flow

SIP in Detail

- There's much more to SIP than we can possibly hope to cover here
 - Go read the RFC!
